

ABSTRACT OF THE DISCLOSURE

A printing unit has at least one cylinder or roller which is mounted in a frame part that is movable by the use of rolls. The rolls are movable between a deployed position and a retracted position. In the deployed position, the rolls support the movable frame part. In the retracted position, the rolls, at least in part, no longer support the weight of the movable frame part, which is now supported, at least in part, on a stationary support by way of a contact area that is different from the rolls.
